External Anatomy of the Fetal Pig

The external anatomy of the fetal pig reveals distinct features that aid in orientation and identification of body regions. This initial examination is crucial for understanding the pig's layout before proceeding to internal dissection. The fetal pig is typically examined in the ventral position to facilitate access to the thoracic and abdominal cavities.

Body Regions and Surface Features

The body of the fetal pig is divided into three main regions: the head, trunk, and tail. The trunk itself consists of thoracic and abdominal segments. Key external features include the snout, eyes, ears, and limbs, each adapted for specific functions.

Skin and Hair

The skin of the fetal pig is relatively thin, covered with fine hair called vibrissae around the snout and eyes. The skin protects internal structures and contains sensory receptors. Pigmented areas may vary depending on the specimen.

Limbs and Hooves

The fetal pig possesses four limbs, each terminating in hooves that are divided into two toes. The forelimbs and hindlimbs show similar anatomical structures including joints, muscles, and nails, which provide mobility and support.

Digestive System Anatomy and Dissection

The digestive system of the fetal pig is complex and essential for nutrient processing and absorption. Dissection focuses on tracing the alimentary canal and identifying accessory organs that contribute to digestion.

Oral Cavity and Pharynx

The oral cavity contains the tongue, teeth, and salivary glands. The tongue aids in manipulating food, while teeth participate in mechanical breakdown. The pharynx serves as a passageway for food and air.

Esophagus and Stomach

The esophagus is a muscular tube that transports food to the stomach. The stomach is a large, sac-like organ where chemical digestion begins through enzymatic activity and acid secretion.

Small and Large Intestines

The small intestine is divided into the duodenum, jejunum, and ileum, where most nutrient absorption occurs. The large intestine absorbs water and forms feces. The colon and rectum are key components of the large intestine.

Accessory Digestive Organs

Accessory organs include the liver, gallbladder, and pancreas. The liver produces bile, stored in the gallbladder, which aids in fat digestion. The pancreas secretes digestive enzymes and hormones regulating blood sugar.

Digestive System Dissection Steps

1. Make an abdominal incision to expose the alimentary canal.
2. Identify and isolate the esophagus leading to the stomach.
3. Examine the stomach's internal structure and openings.

4. Trace the small intestine and locate the duodenum, jejunum, and ileum.
5. Locate the large intestine and its segments.
6. Identify accessory organs and observe their connections to the digestive tract.

Respiratory System Anatomy and Dissection

The respiratory system facilitates gas exchange, supplying oxygen and removing carbon dioxide. Understanding the fetal pig's respiratory anatomy provides insight into mammalian breathing mechanisms.

Nasal Cavity and Pharynx

The nasal cavity filters and conditions inhaled air. It connects to the pharynx, which serves as a shared pathway for respiratory and digestive systems.

Larynx and Trachea

The larynx contains the vocal cords and protects the lower respiratory tract. The trachea is a rigid tube reinforced with cartilage rings, conducting air to the lungs.

Lungs and Bronchial Tree

The lungs are paired organs where gas exchange occurs. The bronchial tree branches extensively within the lungs, ending in alveoli, the site of oxygen and carbon dioxide diffusion.

Respiratory System Dissection Steps

1. Expose the thoracic cavity by carefully cutting through the rib cage.
2. Identify the trachea and trace it to the lungs.
3. Observe the lobes of the lungs and bronchial branches.
4. Examine the diaphragm's position beneath the lungs.

Circulatory System Anatomy and Dissection

The circulatory system transports blood, nutrients, and gases throughout the fetal pig's body. Dissection reveals the heart's structure and major blood vessels enabling circulation.

Heart Anatomy

The heart is a four-chambered muscular organ consisting of two atria and two ventricles. It pumps oxygenated and deoxygenated blood through systemic and pulmonary circuits.

Major Blood Vessels

Important vessels include the aorta, pulmonary arteries and veins, superior and inferior vena cava. These vessels facilitate blood flow to and from the heart and body tissues.

Blood Flow Pathway

Blood flows from the body into the right atrium, then to the right ventricle, and is pumped to the lungs. Oxygenated blood returns to the left atrium, passes to the left ventricle, and is circulated through the body.

Circulatory System Dissection Steps

1. Open the thoracic cavity and locate the heart.
2. Identify the atria and ventricles by external and internal examination.
3. Trace major arteries and veins connected to the heart.
4. Examine the valves and septa within the heart chambers.

Urogenital System Anatomy and Dissection

The urogenital system encompasses the urinary and reproductive organs. Its anatomy varies slightly between male and female fetal pigs but generally includes kidneys, ureters, bladder, and gonads.

Kidneys and Urinary Tract

The kidneys filter blood to produce urine, which travels through ureters to the urinary bladder for storage before excretion. The urethra conducts urine outside the body.

Reproductive Organs

In males, the testes, epididymis, vas deferens, and associated glands are present. Females have ovaries, oviducts (fallopian tubes), uterus, and vagina. These organs are responsible for gamete production and reproduction.

Urogenital System Dissection Steps

1. Expose the posterior abdominal cavity by retracting the intestines.
2. Identify the kidneys and trace ureters to the bladder.
3. Distinguish reproductive organs based on sex.
4. Examine the external genitalia and internal connections.

Nervous System Anatomy and Dissection

The nervous system controls bodily functions and responses through a complex network of neurons. The fetal pig's nervous system includes the brain, spinal cord, and peripheral nerves.

Brain and Cranial Nerves

The brain is protected by the skull and divided into regions such as the cerebrum, cerebellum, and brainstem. Cranial nerves originate from the brain and control sensory and motor functions in the head.

Spinal Cord and Peripheral Nerves

The spinal cord runs through the vertebral column and transmits signals between the brain and body. Peripheral nerves branch off to innervate muscles and organs.

Nervous System Dissection Steps

1. Remove the skull cap carefully to expose the brain.
2. Observe the major brain regions and cranial nerves.
3. Expose the vertebral column and identify the spinal cord.
4. Trace peripheral nerves extending from the spinal cord.

Frequently Asked Questions

What is the purpose of dissecting a fetal pig in anatomy studies?

Dissecting a fetal pig allows students to observe mammalian anatomy and understand organ systems in a way that is comparable to human anatomy due to similarities in structure and function.

How do you identify the sex of a fetal pig during dissection?

The sex of a fetal pig can be determined by examining the urogenital opening; males have the urogenital opening near the umbilical cord, while females have it near the anus, along with a genital papilla.

What are the major organ systems visible during a fetal pig dissection?

The major organ systems visible include the digestive system, respiratory system, circulatory system, nervous system, and urinary system.

Why is the fetal pig used as a model organism in anatomy?

The fetal pig is used because its anatomy closely resembles that of humans in terms of organ placement and structure, making it an excellent model for studying mammalian anatomy.

What are the key differences between fetal pig anatomy and adult pig anatomy?

Key differences include size, developmental stage of organs, and the presence of fetal structures such as the umbilical cord and the ductus arteriosus, which are not present in adult pigs.

How do you properly open the fetal pig to begin dissection?

To begin dissection, make a midline incision from the throat to the pelvic region, then carefully cut laterally to create flaps that expose the thoracic and abdominal cavities without damaging underlying organs.

What is the function of the thymus gland in the fetal pig and where is it located?

The thymus gland is involved in the development of the immune system by producing T-cells; it is located in the thoracic cavity, anterior to the heart and overlying the trachea.

How can you distinguish between the small and large intestines in a fetal pig?

The small intestine is longer, narrower, and more coiled, while the large intestine is shorter, wider, and has a sac-like structure called the cecum attached near its beginning.

What role does the liver play in the fetal pig, and how can it be identified?

The liver processes nutrients and detoxifies substances; it is a large, dark reddish-brown organ located just below the diaphragm, occupying much of the upper abdominal cavity.

Why is it important to study the circulatory system of the fetal pig during dissection?

Studying the fetal pig's circulatory system helps understand mammalian heart structure and fetal circulation, including unique features like the ductus arteriosus and foramen ovale that differ from adult circulation.
