Cell Theory and Types of Cells

The foundation of cell biology is built upon the principles of cell theory and the classification of cells into types. This section will review critical vocabulary related to these fundamental concepts, offering clear definitions and context for terms frequently encountered in chapter 7 cell structure and function vocabulary review.

Cell Theory

Cell theory is a central concept in biology that states three main principles: all living organisms are composed of cells, the cell is the basic unit of structure and function in living things, and all cells arise from pre-existing cells. Key vocabulary associated with cell theory includes **organism**, **unicellular**, **multicellular**, and **prokaryote** versus **eukaryote**.

Prokaryotic and Eukaryotic Cells

Understanding the difference between prokaryotic and eukaryotic cells is essential in chapter 7 cell structure and function vocabulary review. Prokaryotic cells lack a nucleus and membrane-bound organelles, while eukaryotic cells have a true nucleus and complex organelles. Terms such as **nucleoid**, **cytoplasm**, and **organelles** are vital in differentiating these cell types.

Key Organelles and Their Functions

Cells contain various organelles, each with a unique role that contributes to the cell's overall function. This section covers the essential vocabulary related to cellular organelles, emphasizing their structure and function within the cell.

Nucleus

The nucleus is the control center of a eukaryotic cell, housing the cell's genetic material. Important terms here include **chromatin**, **nucleolus**, and **nuclear envelope**. The nucleus regulates cell activities by controlling gene expression and DNA replication.

Mitochondria

Mitochondria are known as the powerhouse of the cell because they generate ATP through cellular respiration. Vocabulary related to mitochondria includes **cristae**, **matrix**, and **aerobic respiration**. Understanding these terms helps clarify energy production processes.

Endoplasmic Reticulum and Golgi Apparatus

The endoplasmic reticulum (ER) and Golgi apparatus are involved in protein and lipid processing and transport. The ER is divided into **rough ER** (studded with ribosomes) and **smooth ER**. The Golgi apparatus modifies, sorts, and packages proteins for secretion or internal use. Terms such as **ribosomes**, **vesicles**, and **cisternae** are relevant here.

Lysosomes and Peroxisomes

Lysosomes contain digestive enzymes that break down waste materials and cellular debris, while peroxisomes are involved in the breakdown of fatty acids and detoxification. Vocabulary includes **hydrolytic enzymes** and **oxidative enzymes**.

Membrane Structure and Transport Vocabulary

Cell membranes control the movement of substances into and out of the cell, maintaining homeostasis. This section reviews terminology related to membrane composition and transport mechanisms, which are integral to chapter 7 cell structure and function vocabulary review.

Phospholipid Bilayer

The cell membrane primarily consists of a phospholipid bilayer, which creates a semi-permeable barrier. Key vocabulary includes **hydrophilic heads**, **hydrophobic tails**, and **fluid mosaic model**, describing the membrane's dynamic nature.

Membrane Proteins

Membrane proteins play important roles in transport, signaling, and cell recognition. Vocabulary relevant to this topic includes **integral proteins**, **peripheral proteins**, **channel proteins**, and **carrier proteins**.

Transport Mechanisms

Cells use various methods to move substances across the membrane. These include passive transport types such as **diffusion**, **facilitated diffusion**, and **osmosis**, as well as active transport mechanisms like **endocytosis** and **exocytosis**. Understanding these terms is critical for mastering chapter 7 cell structure and function vocabulary.

- Diffusion: movement of molecules from high to low concentration
- Osmosis: diffusion of water across a semipermeable membrane
- Facilitated diffusion: passive transport aided by proteins
- Active transport: movement against concentration gradient requiring energy
- Endocytosis: process of engulfing substances into the cell
- Exocytosis: expulsion of materials from the cell

Cellular Processes and Energy Vocabulary

Cells perform numerous processes to maintain life, many of which involve energy transformation and molecular synthesis. This section highlights vocabulary related to these essential cellular activities.

Photosynthesis

Photosynthesis is the process by which plants and some organisms convert light energy into chemical energy stored in glucose. Key terms include **chloroplasts**, **chlorophyll**, **light-dependent reactions**, and **Calvin cycle**.

Cellular Respiration

Cellular respiration converts glucose into ATP, the energy currency of the cell. Vocabulary includes **glycolysis**, **Krebs cycle**, **electron transport chain**, and **ATP synthase**. These terms describe the stages of energy production in mitochondria.

Protein Synthesis

Protein synthesis involves transcription and translation, processes by which cells create proteins based on genetic instructions. Relevant vocabulary includes **mRNA**, **ribosomes**, **tRNA**, and **codon**.

Specialized Cell Structures and Functions

Beyond common organelles, some cells contain specialized structures that support unique functions. This section explores the vocabulary associated with these specialized components, important within chapter 7 cell structure and function vocabulary review.

Cytoskeleton

The cytoskeleton provides structural support, aids in cell movement, and organizes organelles. Key terms are **microtubules**, **microfilaments**, and **intermediate filaments**.

Cell Wall and Extracellular Matrix

Plant cells and some prokaryotes have a rigid cell wall that provides protection and shape. In animal cells, the extracellular matrix supports tissue structure. Vocabulary includes **cellulose**, **peptidoglycan**, and **collagen**.

Flagella and Cilia

Flagella and cilia are hair-like structures that facilitate cell movement or the movement of fluids past cells. Terms such as **axoneme** and **basal body** describe their internal structure and anchorage.
